# Highs and Lows of a transitional MSP

## The ultimate campaign on PSR J1023+0038

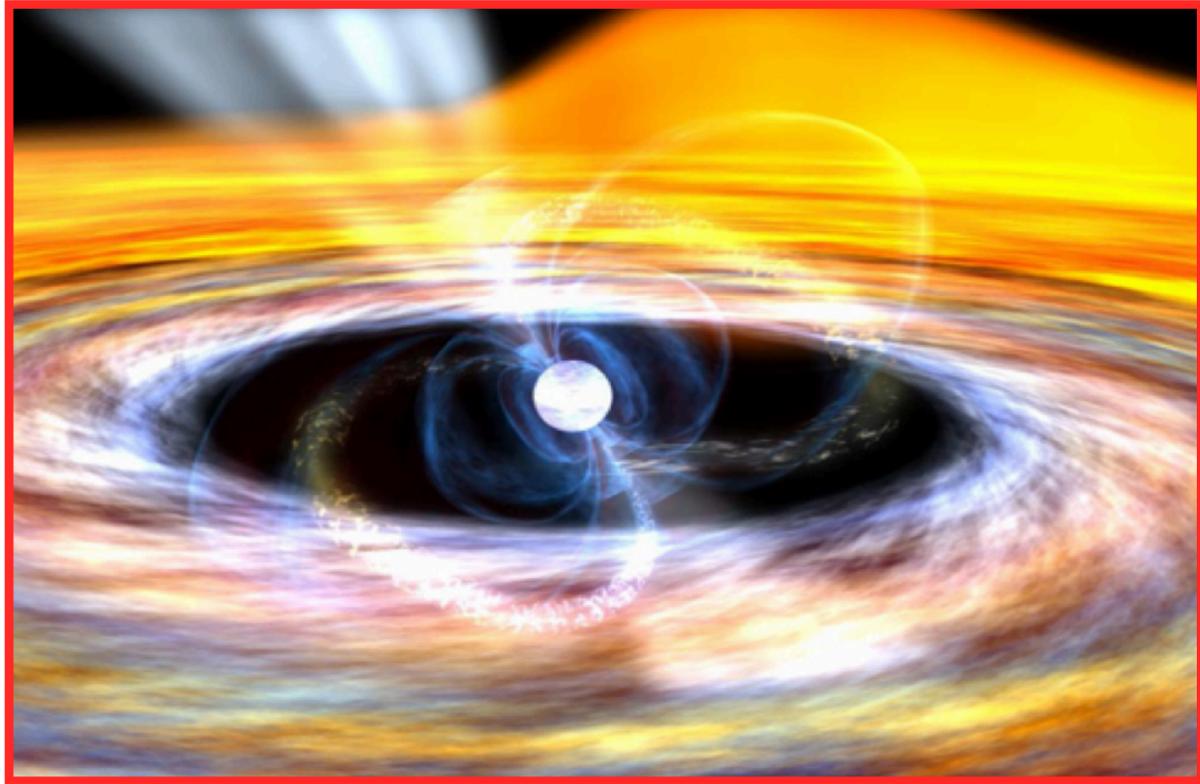

**M. Cristina Baglio**

CNOC XII, Cefalù (PA), 27 September 2022

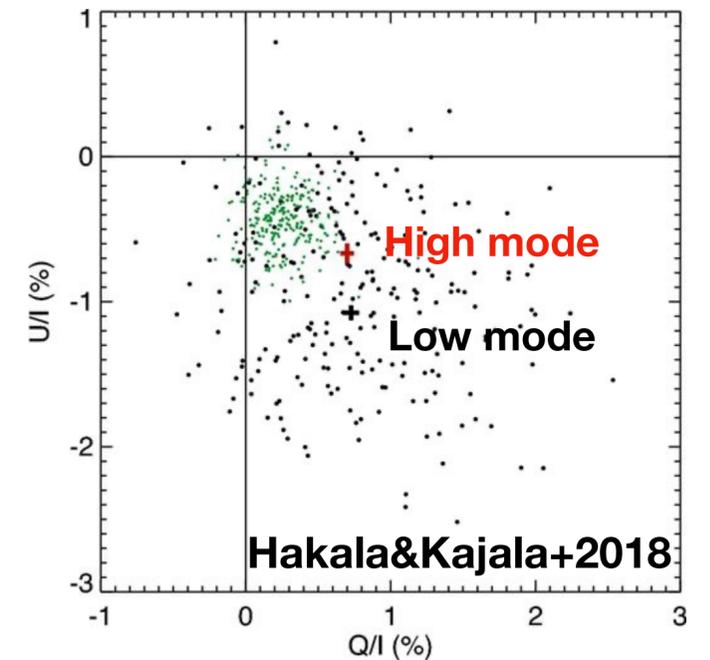

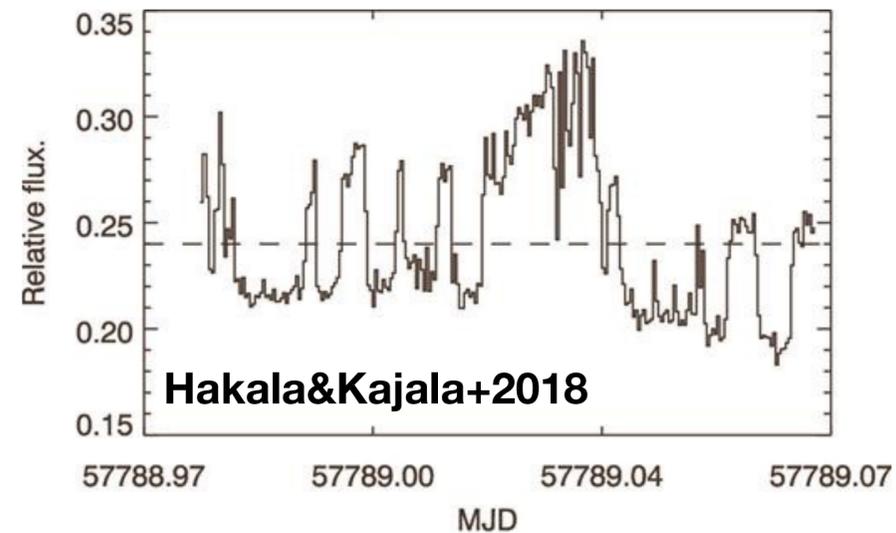

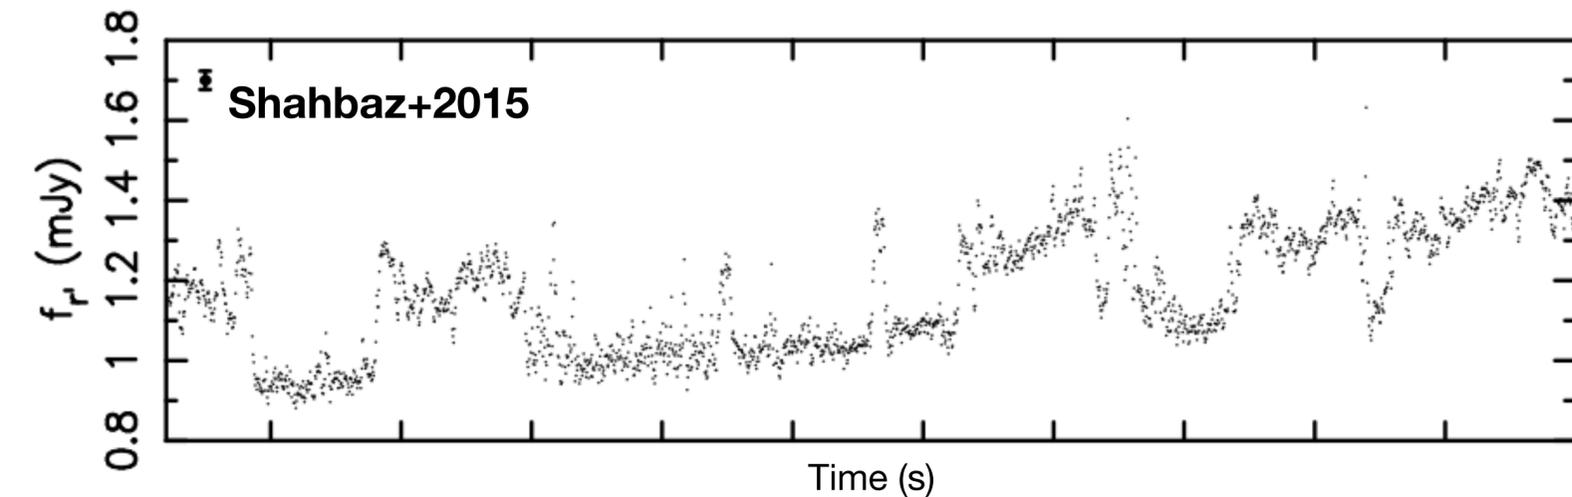

# Accretion states in tMSPs

Both **PSR J1023+0038** and **XSS J12270-4859** show transitions on a timescale of  $\sim 10$ s between a *low* ( $L_x \sim 10^{33}$  erg  $s^{-1}$ ) and a *high* ( $L_x \sim 7 \times 10^{33}$  erg  $s^{-1}$ ) mode. Flares are also observed ( $L_x \sim 10^{34}$  erg  $s^{-1}$ ).  
Bogdanov+2015, Campana+2016

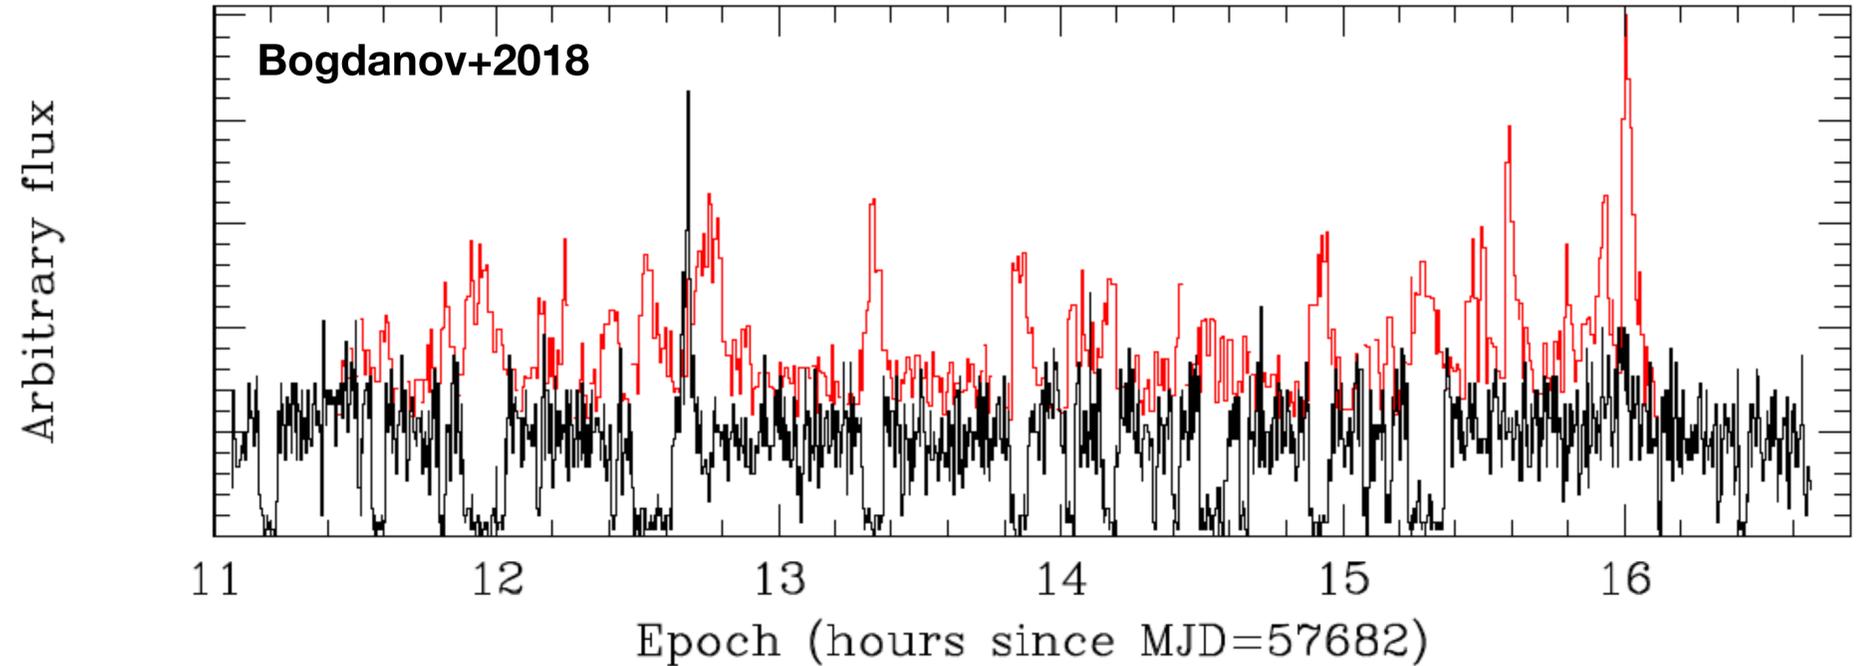

**Pulsations detected during high modes only.**  
**Similar transitions detected also in NIR, optical and optical polarization.**

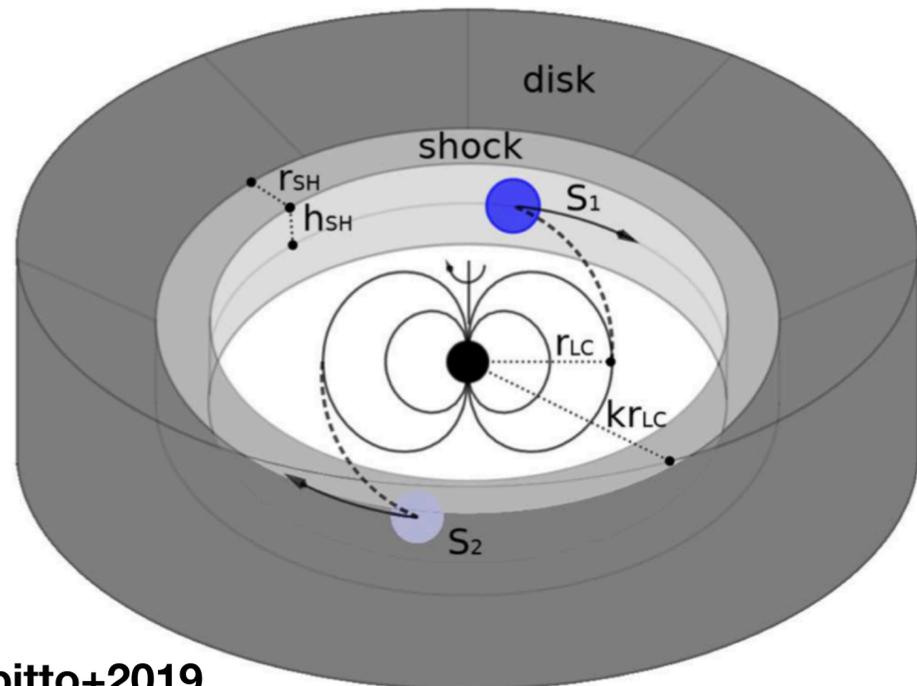

# PSR J1023: what else we already know

**RADIO continuum emission with flat spectral shape: possible compact self-absorbed jet (Deller+2015).**

**RADIO flares during low X-ray modes: possible ejection of optically thin plasmoids (Bogdanov+2018).**

**New important discovery: optical ms pulsations (see Filippo, Alessandro, Arianna talks) with SiFAP2 and Aqueye+**

**The radio pulsar is always active**

## HIGH MODE

**The pulsar wind interacts with the disc  
A shock is generated  
Coherent pulsations from optical to X-rays  
are produced**

## LOW MODE

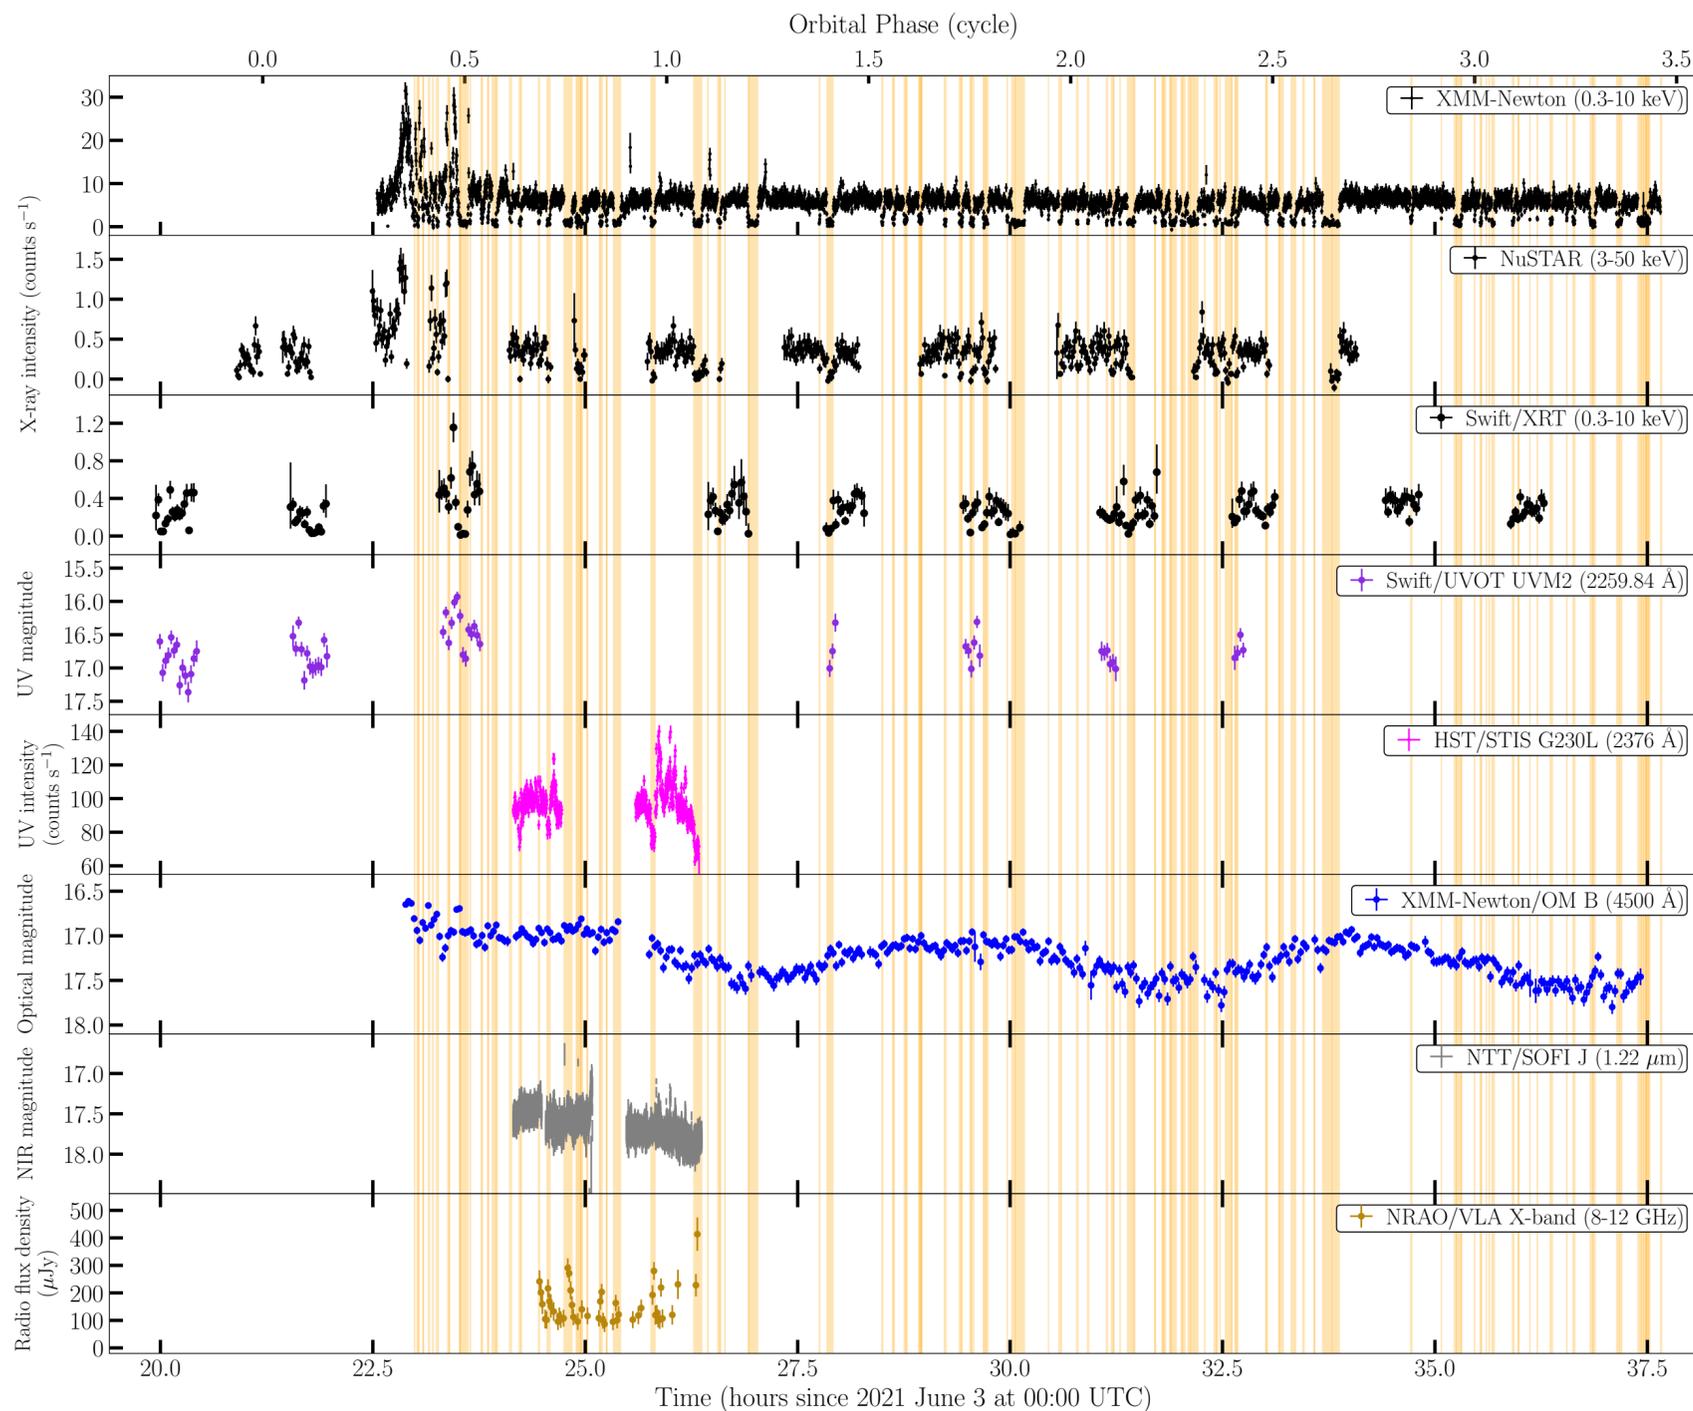

**The shock moves outside the lc radius  
No pulsations are observed**

## FLARING MODE

**The region of shock becomes bigger**

# The ultimate campaign!

2 nights of monitoring in June 2021, many facilities involved.

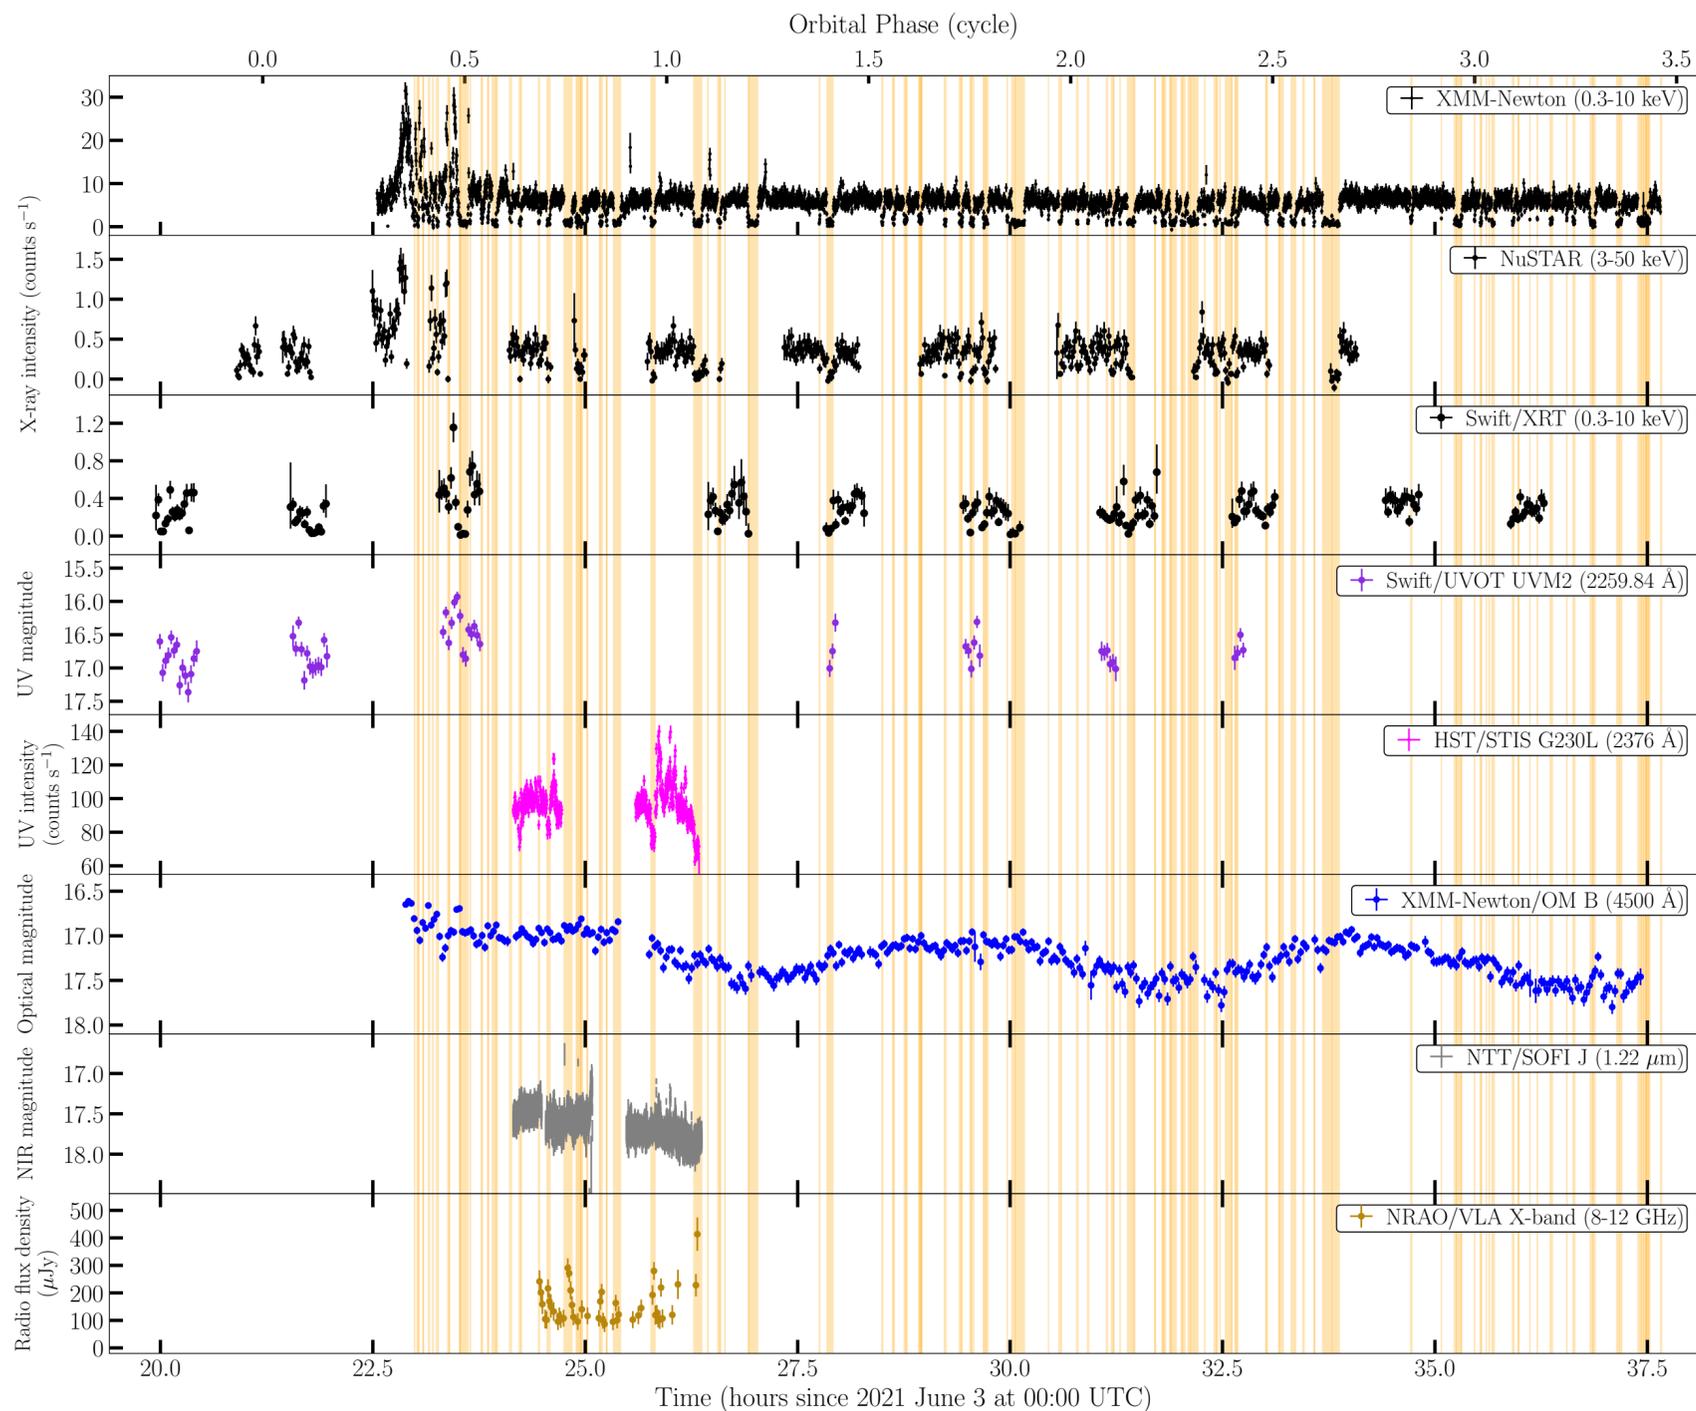

## NIGHT1:

- XMM-Newton (0.3-10 keV)
- NuSTAR
- Swift/XRT
- Swift/UVOT
- HST/STIS
- XMM-Newton/OM B-band
- NTT/SOFI J-band
- VLA X-band (8-12 GHz)

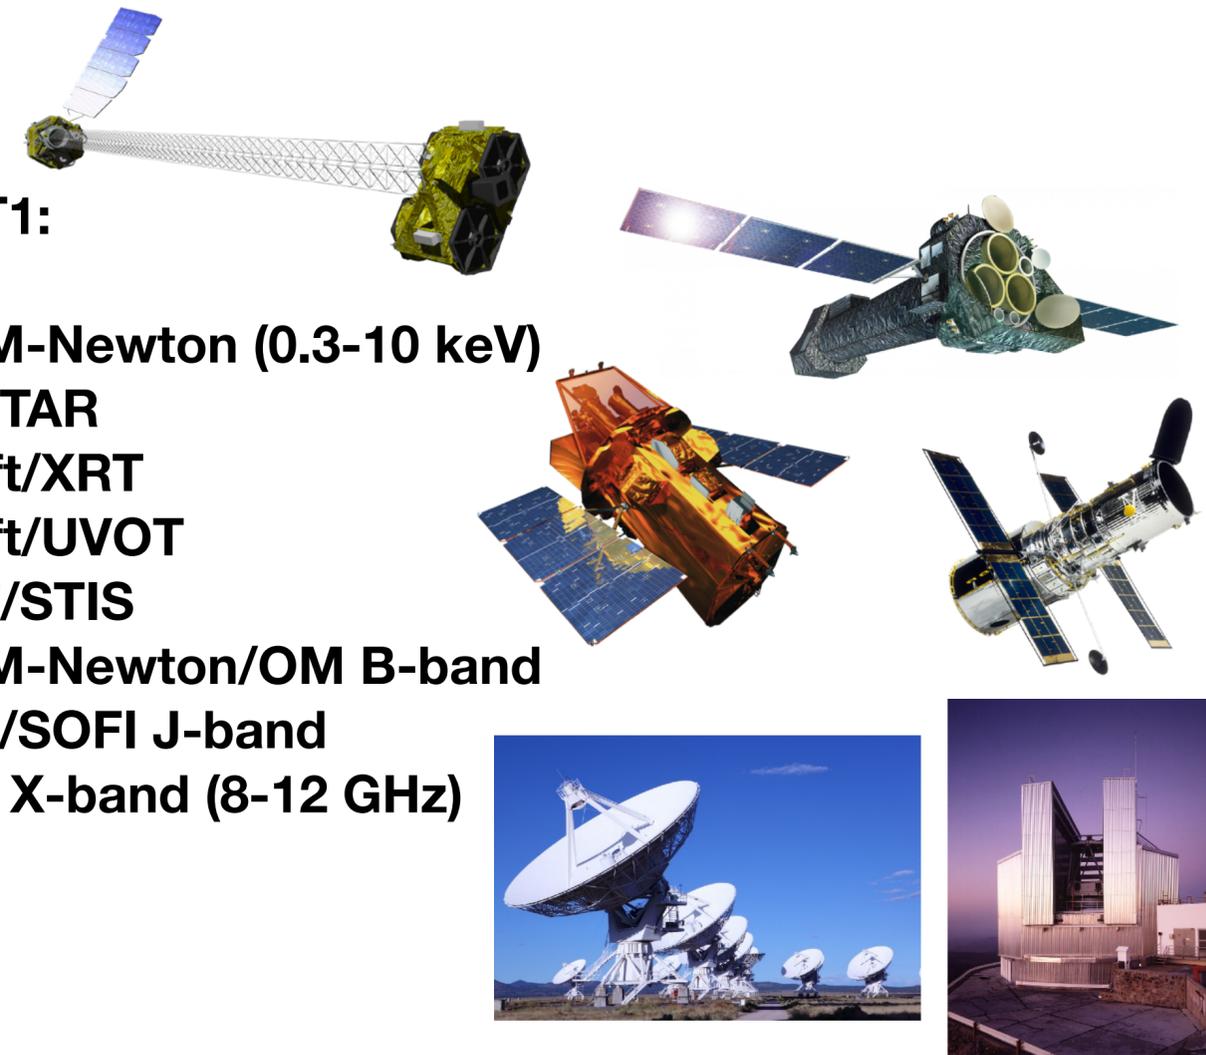

# The ultimate campaign!

2 nights of monitoring in June 2021, many facilities involved.

Baglio, Coti Zelati et al. 2022 (in prep.)

# Highs and lows: a possible scenario

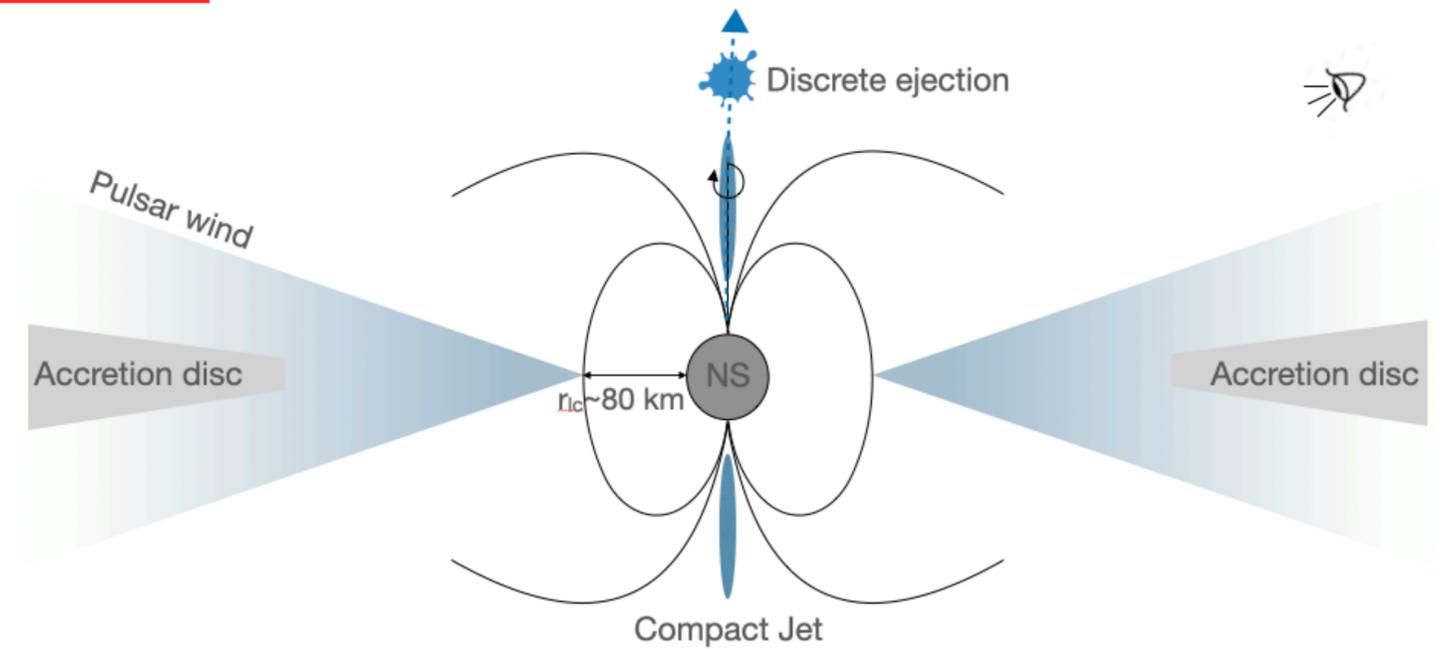

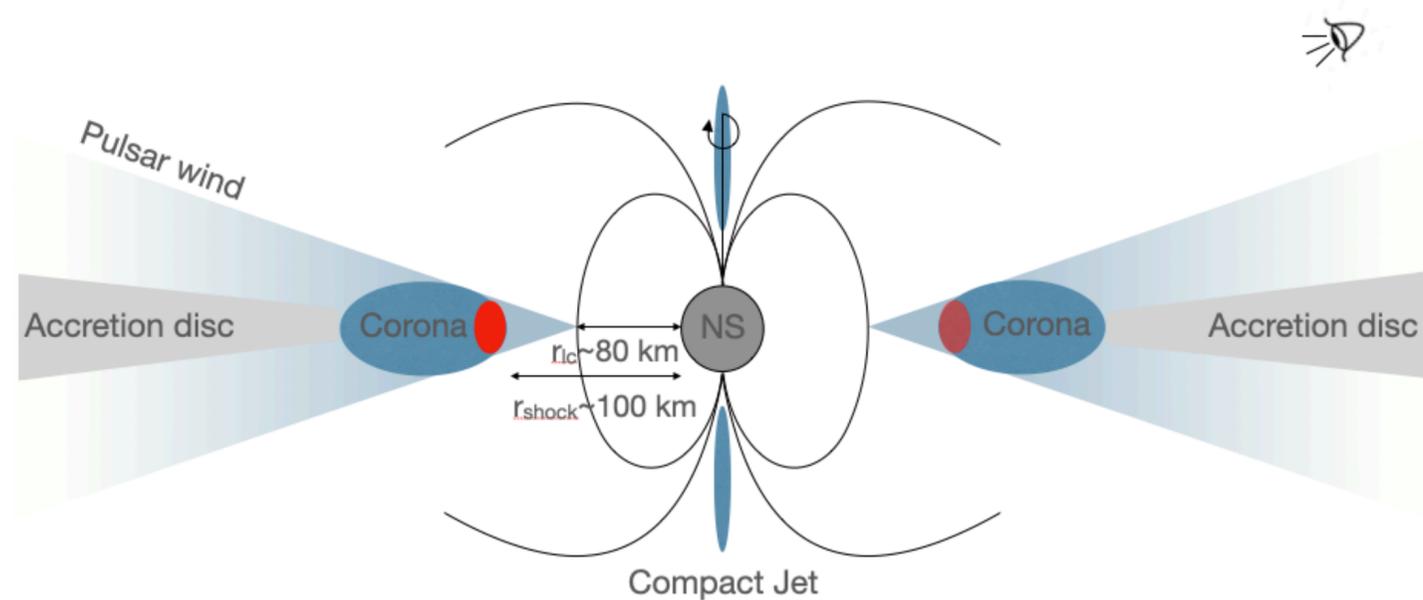

HIGH MODE

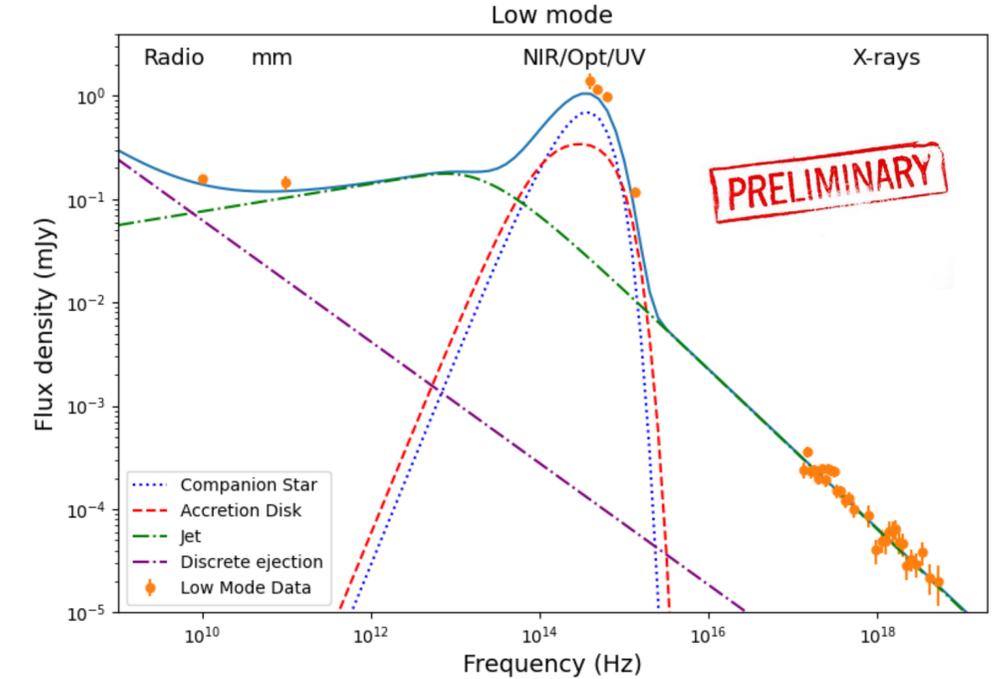

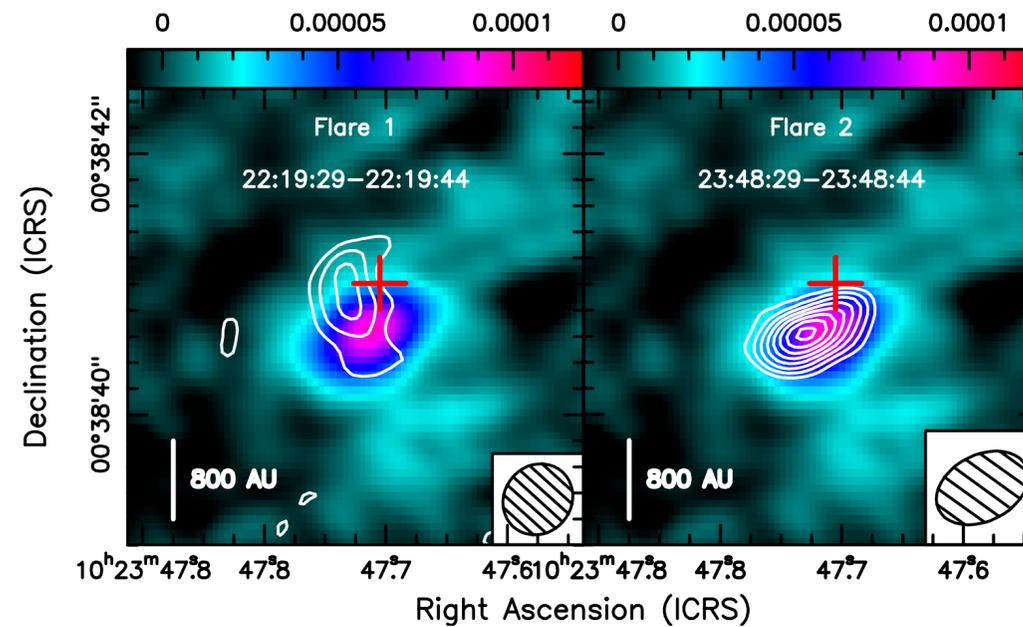

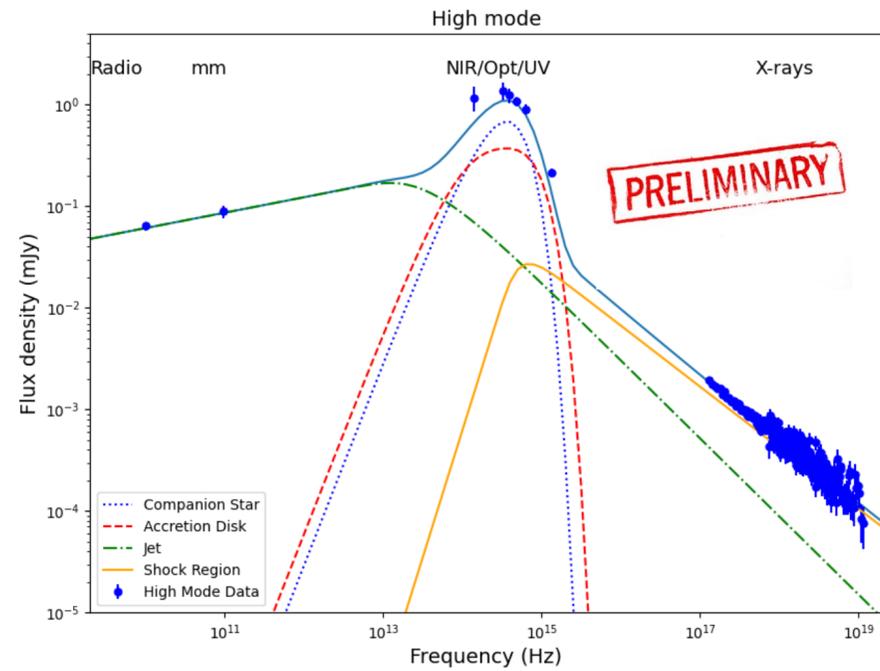

LOW MODE

Baglio, Coti Zelati et al. 2022 (in prep.)

The shock moves out (of a factor  $\sim 20$ ): its contribution in the X-rays is negligible.

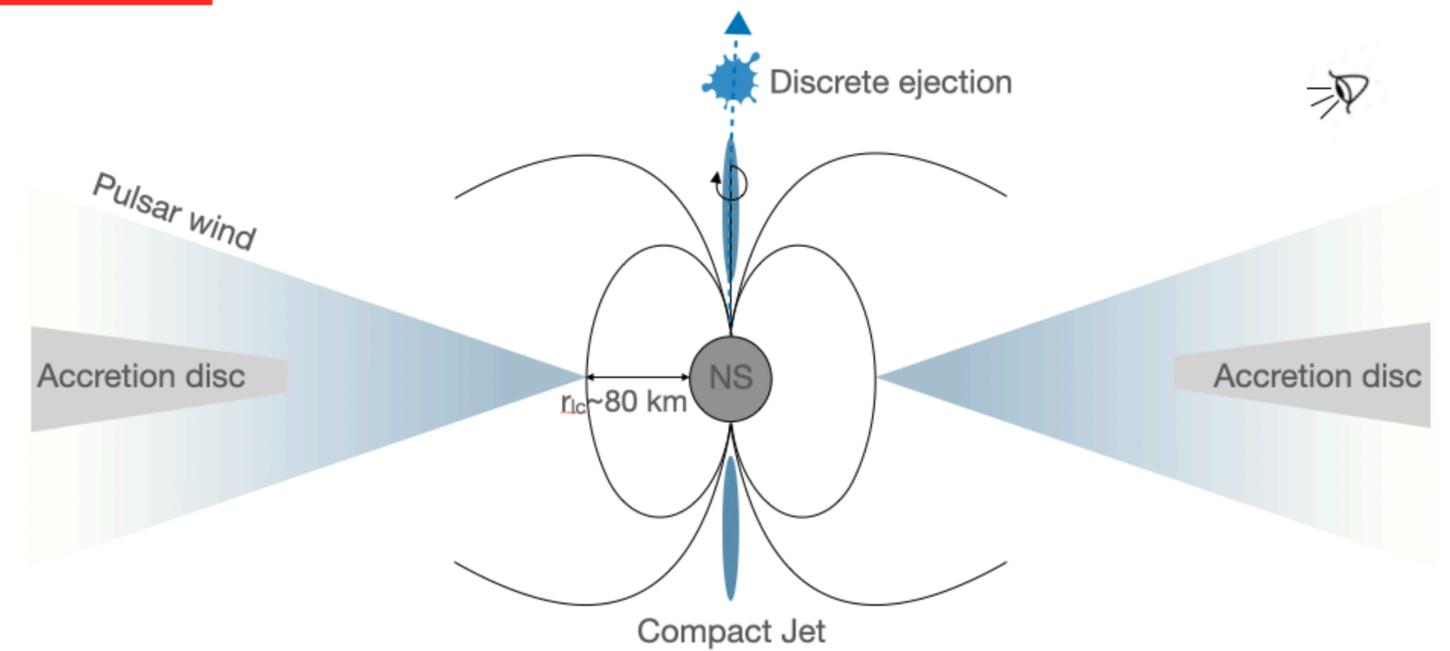

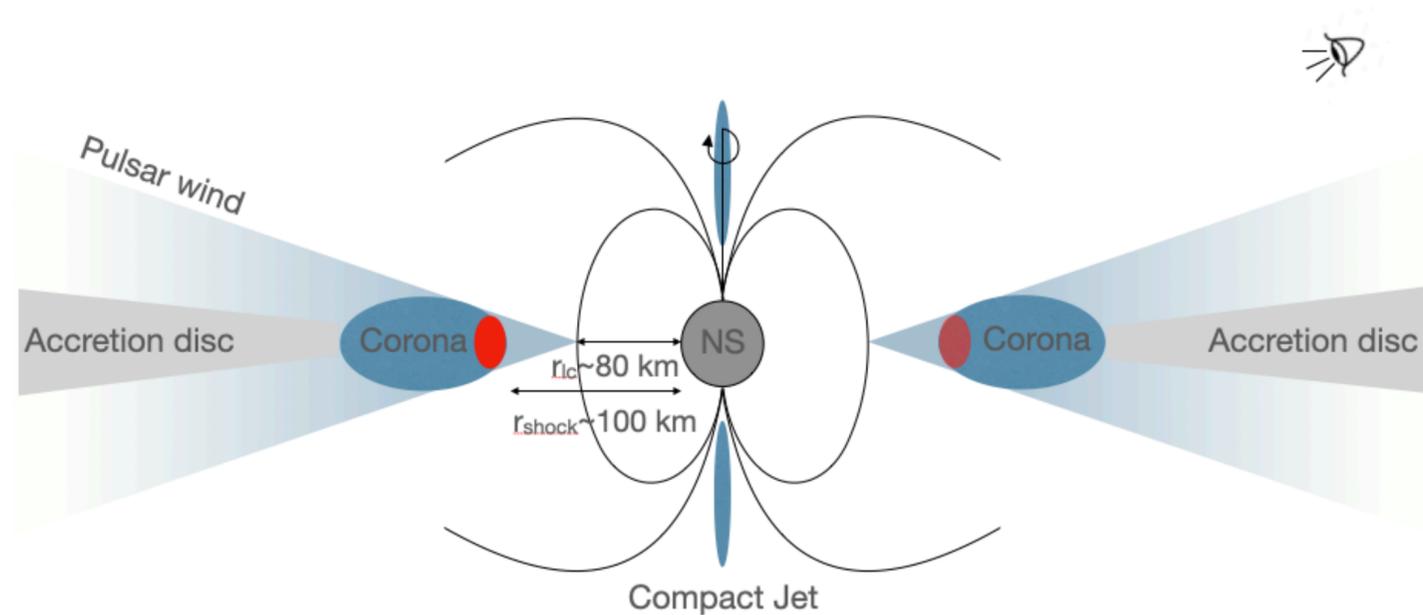

# Highs and lows: a possible scenario

HIGH MODE

LOW MODE

Baglio, Coti Zelati et al. 2022 (in prep.)

The shock moves out (of a factor  $\sim 20$ ): its contribution in the X-rays is negligible.

# Polarization: possible origins & predictions

## 1 - Optically thin emission from the jet

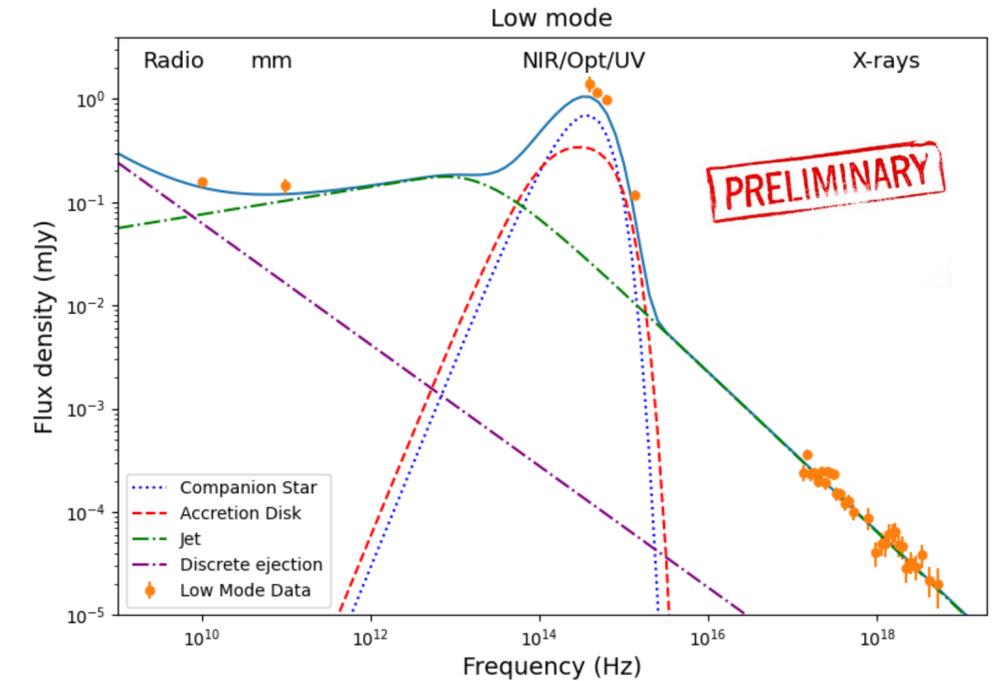

Low average polarization (0.92%).

The compact jet is contributing up to 3% in r-band.

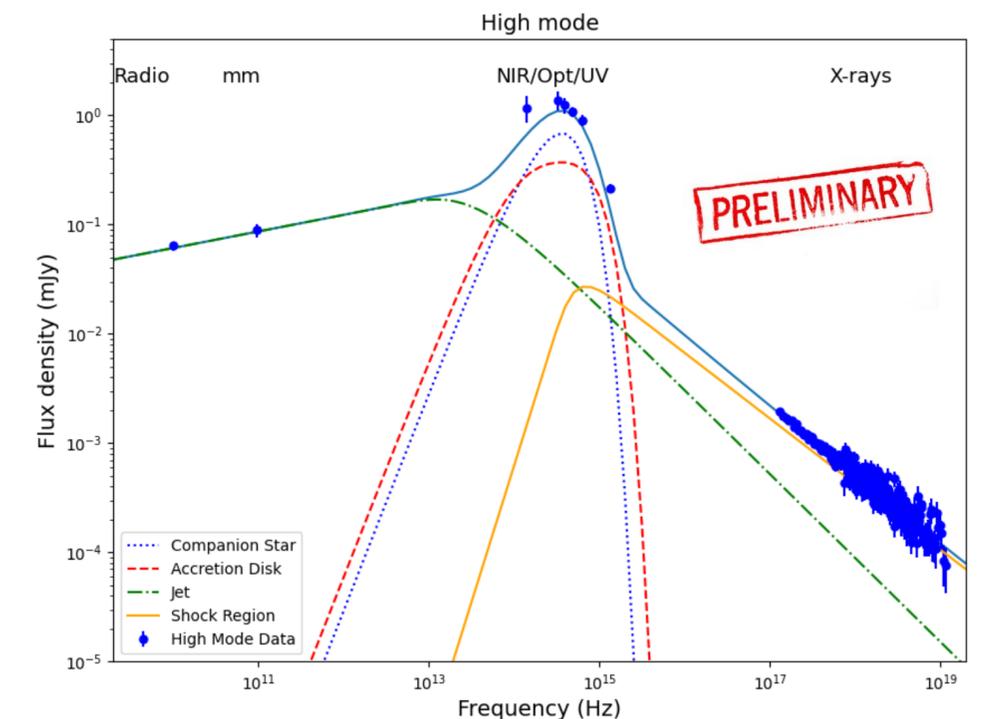

The jet would therefore be intrinsically polarized at 30%.

This would imply a highly ordered magnetic field at the base (~60%)

Prediction of X-ray LP due to the jet of ~12% in the IXPE band (in low mode) and 4% (in high mode): can be tested.

Baglio, Coti Zelati et al. 2022 (in prep.)

# Polarization: possible origins & predictions

## 1 - Optically thin emission from the jet

Low average polarization (0.92%).

The compact jet is contributing up to 3% in r-band.

The jet would therefore be intrinsically polarized at 30%.

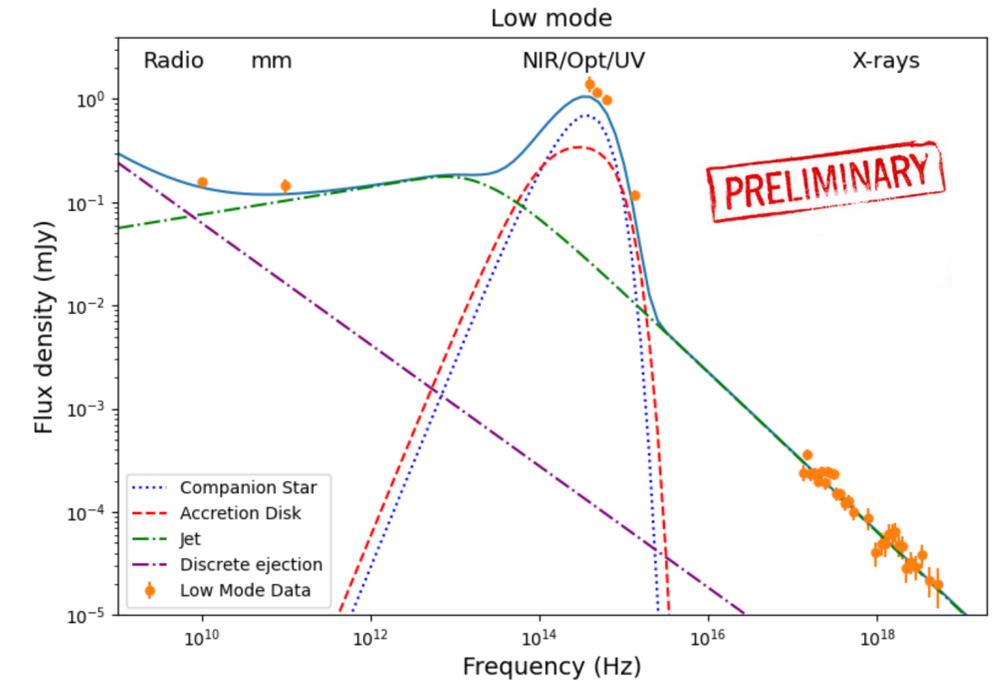

This would imply a highly ordered magnetic field at the base (~60%)

Prediction of X-ray LP due to the jet of ~12% in the IXPE band (in low mode) and 4% (in high mode): can be tested.

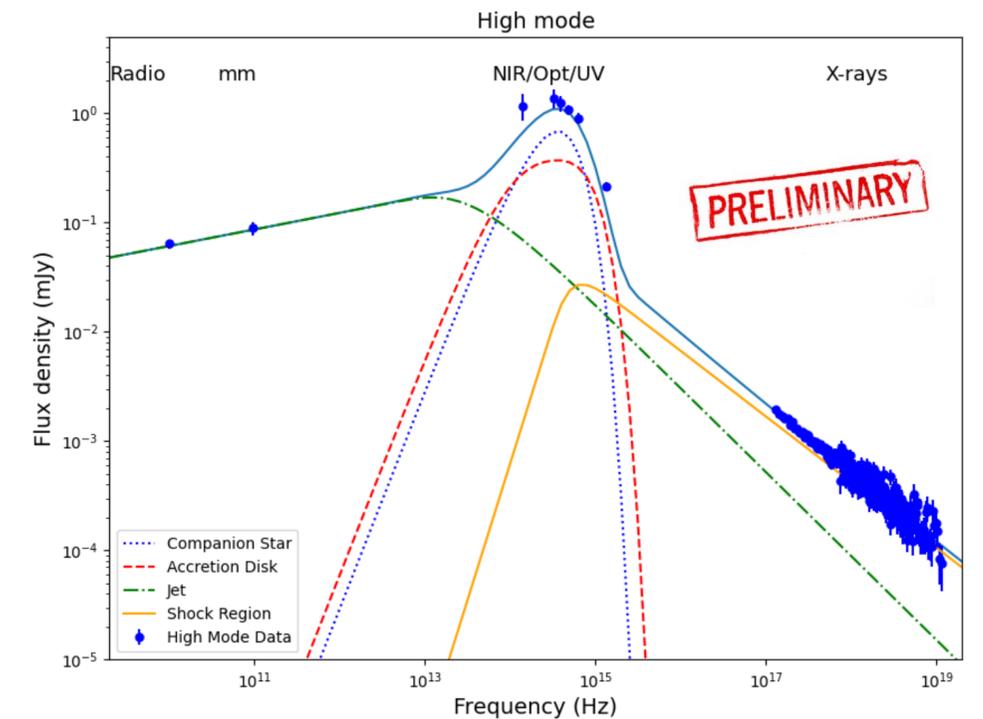

## 2 - Synchrotron in the region of shock

Scenario consistent with the ~lower P in low mode

$$P_{\text{low}} = (0.36^{+0.27}_{-0.35})\% \quad P_{\text{high}} = (0.65^{+0.43}_{-0.42})\%$$

Baglio, Coti Zelati et al. 2022 (in prep.)

# Polarization: possible origins & predictions

## 1 - Optically thin emission from the jet

Low average polarization (0.92%).

The compact jet is contributing up to 3% in r-band.

The jet would therefore be intrinsically polarized at 30%.

This would imply a highly ordered magnetic field at the base (~60%)

Prediction of X-ray LP due to the jet of ~12% in the IXPE band (in low mode) and 4% (in high mode): can be tested.

## 2 - Synchrotron in the region of shock

Scenario consistent with the ~lower P in low mode

$$P_{\text{low}} = (0.36^{+0.27}_{-0.35})\% \quad P_{\text{high}} = (0.65^{+0.43}_{-0.42})\%$$

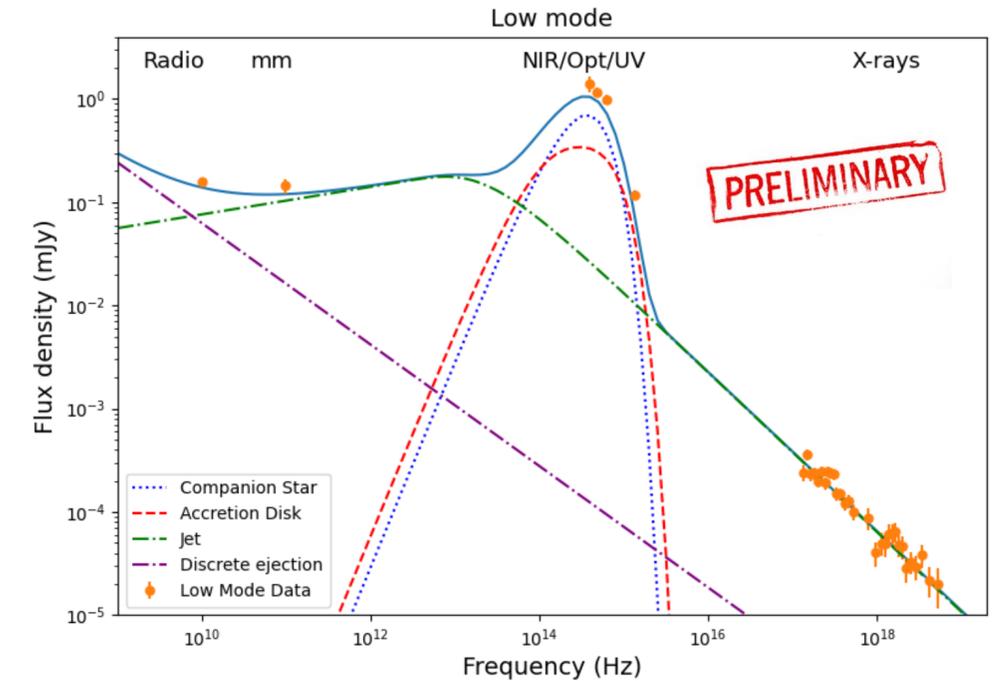

Shock contribution in r-band ~2.7%: intrinsic LP of ~23% in high mode.

If polarization is due to the impulse only (1% of total), then the pulse will be ~90% polarized!

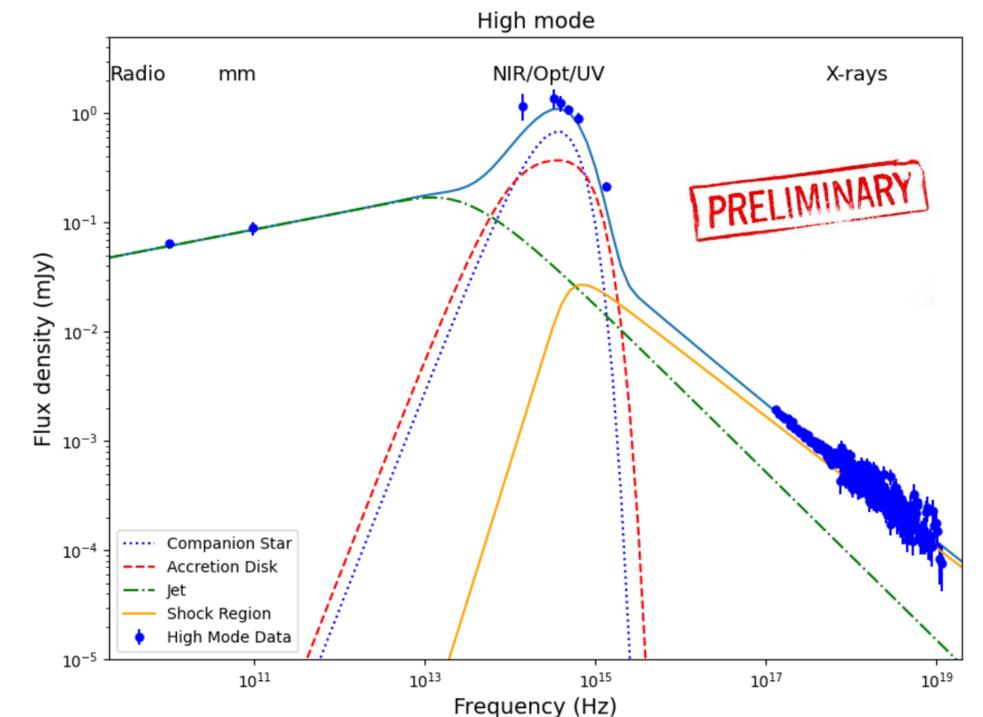

This can be tested with high time-resolution optical polarimetry.

Shock contribution of ~83% in X: X-ray pol of ~19% with IXPE.

Baglio, Coti Zelati et al. 2022 (in prep.)

# Conclusions

The ultimate campaign on PSR J1023 performed in 2021 was extremely successful.

We put together a new scenario which can explain most of the phenomenology:

Radio/X-ray anti-correlation

Flares in the mm at the high/low mode switching

Mode switching in the X-rays

Optical - to - X-rays ms pulsations

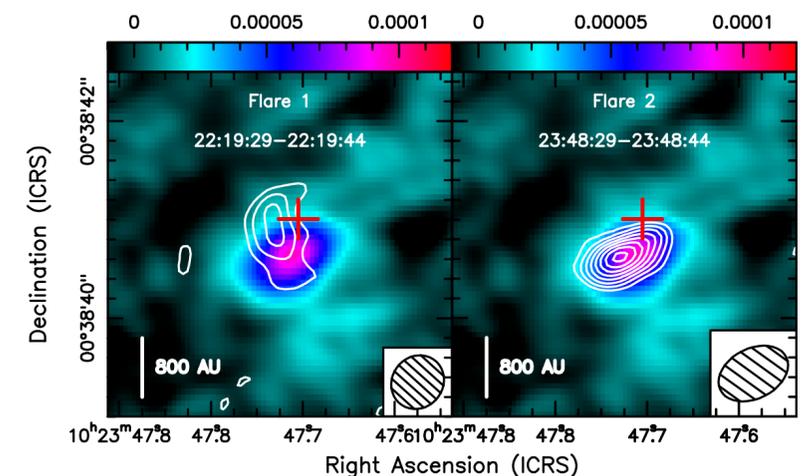

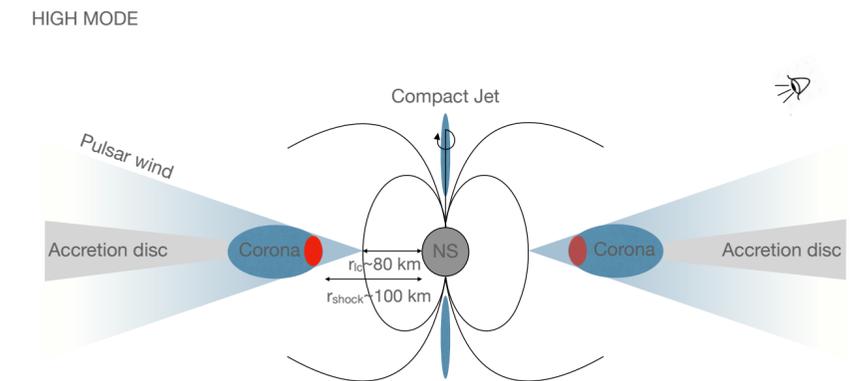

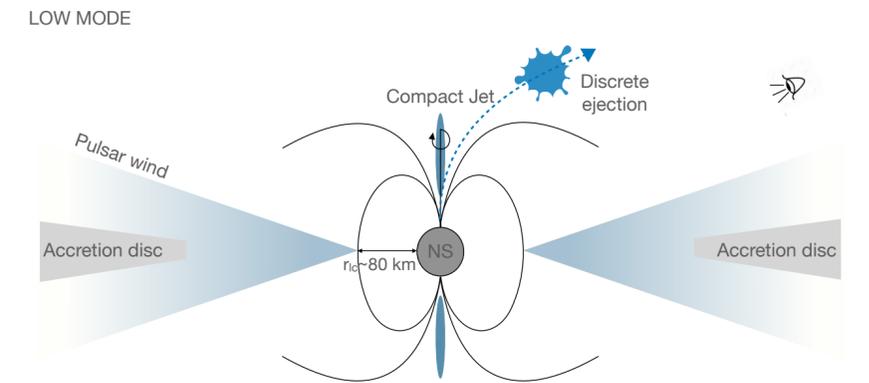

Polarization in the optical

We report on the first observations in the mm of a tMSP.

We explain why 1023 has an anomalous behavior on the radio/X-ray luminosity plane.

We could make predictions for X-ray polarization and high time-resolution optical polarimetry.

Future missions/instruments/campaign will be able to test the predictions and possibly confirm the scenario.
